

AES GCM (Gunn High school, March 29/30, 2016)

- Today: Tip of crypto ice berg
 - Online demo: google.com uses AES-GCM
- Goal: Build it From scratch

What is a cipher? Algs E & D

$E(\text{Key}, \text{msg}) \rightarrow \text{cipher-text}$

$D(\text{Key}, \text{cipher-text}) \rightarrow \text{message}$

example cipher: one-time pad

message: H E L L O W O R L D

ASCII:

48 45 4C 4C 4F 20 57 4F 52 4C 44

random key:

21 34 52 71 23 4A 2B 91 80 57 98

cipher-text:

69 79 9E BD 72 6A 82 E0 02 A3 E2

⊕ no carry/
across bytes

How does decryption work?

Shannon: (1949) If key is random
then ciphertext "reveals nothing" about message

Problem: Key is really big !!

Solution: Pseudorandom generator (PRG)

Decryption works by subtraction.

How to build PRG ??

(1) Bad example: $G(\text{key}) = \boxed{\text{key} | \text{key} | \text{key} | \dots | \text{key}}$

\Rightarrow Show code. They write decryption.
show that using wrong key doesn't decrypt.

Attack 1: letter frequency

Show code. \Rightarrow insecure even though file looks encrypted

Attack 2: Known prefix

FROM: DABO / private data

Key \rightarrow

//////////

\oplus

ciphertext \rightarrow

//////////

\Rightarrow Given ciphertext and prefix of msg
Eve can recover entire msg.

Property of a secure generator:

For random key k :

$G(k)$
//////////

cannot predict from a prefix.

Good generator:

The AES block cipher

Key secret \Rightarrow output always looks random.

$PRG(k) :$

$AES(k, 0)$	$AES(k, 1)$	$AES(k, 2)$	\dots
-------------	-------------	-------------	---------

128 bits 128 bits 128 bits

CTR mode

\Rightarrow show code. show that letter freq attack
doesn't work.

Problem: what if we encrypt two files under same key?

m_1 - file #1, m_2 - file #2

$$- \begin{cases} c_1 = E(\text{key}, m_1) = m_1 \oplus f(\text{key}) \\ c_2 = E(\text{key}, m_2) = m_2 \oplus f(\text{key}) \end{cases}$$

$$(1) \quad c_1 = c_2 \quad \Rightarrow \quad m_1 = m_2$$

$$(2) \quad c_1 - c_2 = m_1 \ominus m_2$$

\Rightarrow enough to recover both messages

Solution: randomness

During encryption chose a random starting point
for counter.

$E(\text{key}, m)$: 1. choose random 128-bit IV

2. $\boxed{\text{AES}(K, \text{IV}) \mid \text{AES}(K, \text{IV}+1) \mid \text{AES}(K, \text{IV}+2) \mid \dots}$

ciphertext

\oplus

\boxed{m}

$\boxed{\text{IV}}$

⇒ show code

Run twice to show different ciphertexts

Problem: no integrity

⇒ show changing ciphertext w/o detection

To: dabb ⇒ To: josh

Solution: Message Auth. Code (MAC)

Security: attacker sees many valid transmissions,
cannot create a new valid transmission

An example secure MAC: (Carter-Wegman)

data:

128	128	128	128	128	128
d_5	d_4	d_3	d_2	d_1	d_0

$$F(X) = X^6 + d_5 X^5 + d_4 X^4 + \dots + d_1 X + d_0$$

key = (K, s) two 128-bit values

$s(\text{key}, \text{data})$: choose random IV , set $r \leftarrow \text{AES}(k, IV)$

$$\begin{aligned} \text{compute: } t &\leftarrow F(s) + r \pmod{2^{128} + 51} \\ &= s^6 + d_5 s^5 + d_4 s^4 + \dots + d_0 + r \pmod{2^{128} + 51} \end{aligned}$$

output: $[IV, t]$

\Rightarrow show code: show that changing CT results in rejection.

This is a variant of AES-GCM.
